86 Aberrant Expression of Oct-2, Spi-B, and Id2/Id1 Is Associated with Repression of Plasma Cell Differentiation in Waldenström's Macroglobulinemia

Program: Oral and Poster Abstracts
Type: Oral
Session: 622. Non-Hodgkin Lymphoma - Biology, excluding Therapy: Building a Better Crystal Ball - Cellular and Molecular Strategies for Risk Stratification in Lymphoma
Sunday, December 11, 2011: 4:45 PM
Room 33 (San Diego Convention Center)

Waldenström's macroglobulinemia (WM) is a lymphoplasmacytic lymphoma characterized primarily by tumor infiltration of lymphoplasmacytic cells (LPC) in the bone marrow (BM) and presence of an IgM monoclonal gammopathy. WM LPC exhibit deficiencies in the ability to differentiate from mature B-cells to plasma cells. We therefore analyzed the expression of several genes involved in B-cell differentiation by real time RT-PCR, including Ets factors, basic helix-loop-helix (bHLH) E proteins, as well as inhibitors of DNA binding (Id) proteins which antagonize E protein activity. Comparison of bone marrow $CD19^+$ B cells obtained from 12 untreated WM patients versus 15 age-matched healthy donors showed that in WM LPC, expression of the Ets factor Spi-B was increased four-fold, Id2 and Id1 were decreased three-fold and ten-fold, respectively, while transcript levels of E proteins were similar between these two groups. Following cytokine induced differentiation of primary $CD19^+$ cells into $CD38^+CD20^-$ plasmablasts, we observed that Spi-B and Id2/Id1 expression levels were significantly decreased and increased, respectively. Furthermore, ectopic expression of Spi-B in primary peripheral blood $CD19^+$ cells from healthy donors inhibited plasma cell differentiation which was associated with decreased transcription levels of BLIMP1, XBP-1 spliced form, and IRF4. Over-expression of Spi-B in BCWM.1 WM cells also resulted in repressed expression of BLIMP1, XBP-1 spliced form, and IRF4. Conversely, knocking down of Spi-B in BCWM.1 WM cells increased IRF4, Id2, and Id1 expression. Importantly, in lentiviral transduced primary WM bone marrow $CD19^+$ cells, knocking down of Spi-B induced $CD38^+CD20^-$ plasmablast formation which was related to increased expression of BLIMP1, XBP-1 spliced form, IRF4, and Id2. Moreover, knocking down of Spi-B in primary WM LPC led to decreased Bcl-2 expression. Since in mice Spi-B is a direct target of OBF-1, which forms a ternary complex with the POU proteins Oct-2 or Oct-1 to interact with the conserved octamer site in promoter region, we next evaluated their roles in WM. While transcript levels of OBF-1 and Oct-1 were similar, transcript levels of Oct-2 were three-fold higher in WM LPC versus healthy donors. Knocking down of Oct-2 in BCWM.1 WM cells decreased Spi-B, Id2, and Id1 expression. In addition, chromatin immunoprecipitation (ChIP) confirmed the presence of Oct-2 and OBF-1 in the human *Spi-B* and *Id2* promoter region. These data suggest that Oct-2 together with OBF-1 regulates Id2/Id1 in concert with Spi-B during B-cell differentiation. These findings establish for the first time the molecular hierarchy among Oct-2, Spi-B, and Id2/Id1 in human B-cells. The results also suggest that aberrant expression of these transcription factors plays a critical role in the pathogenesis of WM by repressing factors involved in plasma cell differentiation while promoting WM LPC survival through Bcl-2.
